

Assignment 12 -Objects

A. Describe Your Objects

The objects I plan to use on my fitness product website are FitnessProgram objects, which represent the different training packages that Coach Kelvin offers to clients. Each FitnessProgram object stores essential data, including the program's name, like Starter Package or Champion Package, duration in months, total price in dollars, an array of features that describes what's included, like workout plans, nutrition guidance, and check-ins, and the targetLevel indicating which fitness experience level the program is designed for: beginner, intermediate, or advanced. These objects need to do key tasks through their methods: getMonthlyPayment(months) calculates how much a client would pay per month if they spread the cost over a specified time period, getDescription() generates a formatted summary of the program's details for display on the website, isAffordableFor(budget) checks whether the program fits within a client's budget, and comparePrice(otherProgram) calculates the price difference between two package. When potential clients visit the programs page, they need to understand what each package offers (getDescription), determine affordability (isAffordableFor), calculate flexible payment options (getMonthlyPayment), and compare different packages to find the best fit for their transformation goals (comparePrice), making the FitnessProgram object a practical tool for helping clients make informed purchasing decisions

B. Draw Your Object Model
